
For each $2 \leq s \leq 240$, convexity of the complete core in $x = s/j$ reduces every $j > 80$ to two common endpoints.

The old 0.257 failure passes; the common radius reaches 9/32, where tail $= 0.778542$ and transport $= 0.996211$.

At 0.282, the active fixed point still closes but transport is $1.000375 > 1$: this is a sufficient-bound failure only.

Finite degree points are regressions. The reduced-system theorem does not prove three-dimensional Navier--Stokes regularity.
