

Finite quartic target scan in the invariant shear chain

$A^4 \widehat{G}_4 / (A^2 \widehat{G}_2) = -(\varepsilon^2 / L^2) R_{L,M,m}$ · 461 distinct triples · 7.495 billion ordered paths · finite evidence only

Numerical reliability: maximum cancellation condition 3,860.6; the observed maximum was recomputed at 60 decimal digits; relative long-double discrepancy < 5.6e-15.

Interpretation: positive R means the quartic target opposes the quadratic target. No M-growth appears in the archived range, but positivity and a uniform bound outside this finite set remain unproved.

Next theorem: a smooth weighted four-point Rudin-Shapiro correlation estimate uniform in L, M, and m.
