

# One flattened high shell sustains a growing coherent output set

Exact target output:  $d_m(t_H) = me^{-m^2 t_H} \sum_{n=0}^{L-1} (1 - e^{-2R_{m-1,n}^2}) / (2R_{m-1,n}^2)$ , with  $H = 4LM$ .

Formal scope: 4,190,209 packet modes, 29,822,521 interaction pairs, 16,760,836 tensor prefixes, and 24/24 exact checks. Display curves use floating point only for presentation.

Conclusion: output multiplicity and isotropic square functions do not force an extra shell factor in the first critical Picard iterate. This is not norm inflation, nonlinear remainder control, or a regularity proof.
