

(a) Certified radius ladder

(b) All-order tail bound by input charge at $r^* = 397/2000$

(c) Exact proof gates and nearby control

The all-order charge-column maximum is 0.689601 at $s = 162$; one analytic sector closes every $s \geq 241$ at 0.473943.

Charge resolution raises the common certified radius from 59/500 to 397/2000; the fixed-charge disk grows by $4.76031 \times$.

Transport is now the binding gate: $0.999410 < 1$ at the target, while the same sufficient bound is $1.002543 > 1$ at 0.199.

Finite columns are regressions only. This reduced-system theorem does not prove three-dimensional Navier--Stokes regularity.
