

The quartic transfer closes only after a lifted state system

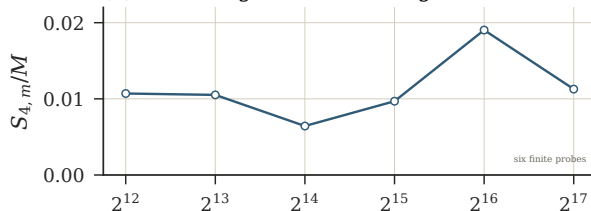

Exact: time-layer factorization + 8-state cubic lift · Open: integrated norm needed for $|S_{4,m}| \leq C L^2 M$

(a) Exact state closure

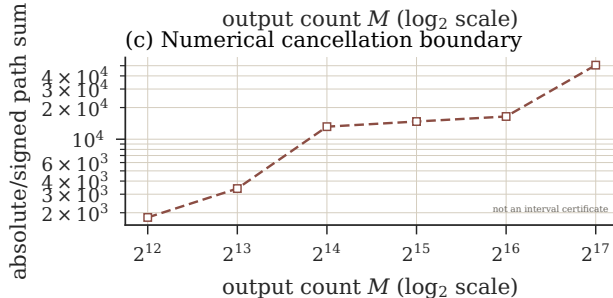

Gaussian half-block restrictions change with scale:
non-autonomous integrated transfer

(b) Heat-weighted hostile targets

(c) Numerical cancellation boundary

Interpretation: the finite heat-weighted probes do not show the unweighted growth, but only a common norm or a supercritical carry cycle can decide the all-index $O(M)$ question.
