

Temporal observables: miss, detect, or overpay?

R0.74P exact-family comparison | analytic bounds, not simulation | NOT CLAY

A Positive-order window masses lose the target

decay term $-\beta \log_{10} K^*$ (additive $\log_{10} C$ suppressed)

PROVED: $\log_{10}(C_{\sigma}/T^*) \leq \log_{10} C - \beta \log_{10} K^*$

Rate-only curves omit $\log_{10} C$; fixed $\sigma > 0$, nonuniform as $\sigma \rightarrow 0$.

B Exact exponential-rate ledger

Rate relative to T^* , in units $a=2m/3$

observable	rate	verdict
window $\sigma=1/4$	$\leq -1/4$	misses
window $\sigma=1/2$	$\leq -1/2$	misses
window $\sigma \geq 1$	≤ -1	misses
matched target component v_j	$= 0$	detects
over-weighted target lower	$\geq 640/43$	overpays

Target component only: $v_j \sim T^*$.

OPEN: no full upper bound for $Y_2(sf)$.

The over-weighted lower bound pays $\Gamma^{-1/2}$.
