

Fixed-small-coupling endpoint scaling

$A_q = \delta q^2$ · fixed- δ panels use $\delta = 1/128$ · target (1, 1) · roots (.1, .2)/ q^2 · finite coset $R = 40$

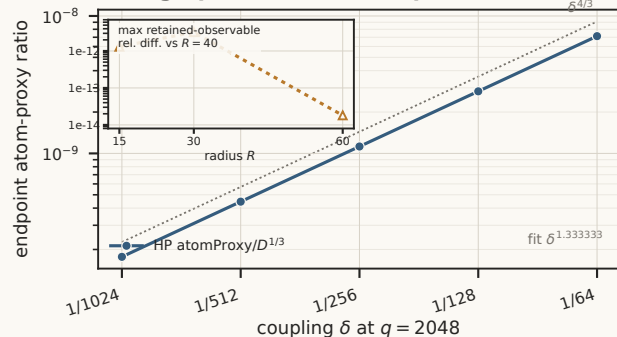

A Fixed-delta q scaling (indexed)

B Endpoint-normalized evidence layers

C High-precision $\delta^{4/3}$ collapse

Evidence boundary: high-precision algebra and finite retained-coset corroboration are separate. atomProxy is not multiplier-locked J ; finite coset is not DNS.

$\delta = 1/128$ is not proved inside the existential continuum IFT radius; no spectral-convergence, universal $D^{1/3}$, or regularity claim is made.
