

(a) Certified radius ladder

(b) Exact transport endpoints at $r^* = 32/125$

(c) Exact proof gates and adjacent control

Convexity reduces every input slope to $x = -1$ or $x = 2$; monotonicity makes $j = 1$ the exact polynomial maximum.

The common certified radius rises from 397/2000 to 32/125; the fixed-charge disk grows by $2.14505 \times$.

At 0.256, transport is $0.862199 < 1$ and the active tail is $0.994409 < 1$; at 0.257, only the tail bound fails.

Finite columns are regressions only. This reduced-system theorem does not prove three-dimensional Navier-Stokes regularity.
