

R0.43 charge-implied degree-floor diagnostics

Exact GMP bounds; $s \geq 241$ and $s \leq 2j$ sharpen the uniform input floor from 81 to 121

(a) Support-implied input degree

(b) Large-sector bound bridge

(c) Complete gates at $r = 0.330$

(d) Adjacent tail-bound bracket

Theorem: $j \geq \max \{N + 1, \lfloor S/2 \rfloor\}$ lowers only the positive large-charge degree prefactor.

Target: legacy 1.002872 becomes 0.998881 at $r = 0.330$; all active and canonical-stretch gates close.

Regression: 21 finite exact large-charge columns lie below the analytic sector bound; they do not prove it.

Scope: reduced canonical edge generating system, not the full three-dimensional Navier-Stokes equation.
