

Coherent fixed-output saturation of the normal Fourier-Leray channel

Exact packet: $p_N = (N, 0, 0)$, $q_N = (-N, 1, 0)$, $\hat{U}(p_N) = c_N e_2$, $\hat{V}(q_N) = c_N e_3$; every forward term is $c_N^2 e_3$ and every exchanged term is zero.

Formal scope: 200,000 coherent pairs, 400,000 ordered output pairs, 1,000,000 all-index regressions, 20/20 checks; exact integer audit. The plotted heat curve is presentation data for an analytic identity.

Conclusion: signed fixed-output aggregation, exchange symmetrization, one-shell localization, and instantaneous heat evolution do not force decay. This is not a Duhamel estimate or a Navier-Stokes regularity proof.
