

R0.44 common-slope active-tail diagnostics

Exact GMP bounds; one shared $x = s/j$ replaces independent termwise slope maxima in the complete positive sum

(a) Complete common-slope envelope at $r = 0.370$

(b) Removed termwise slope loss

(c) Three exact radius controls

Theorem: the positive envelope $H_r(x) = \sum c_{i,q} d_{\beta,q} |x - q|/3$ is convex on $0 \leq x \leq 2$.

Target: $r = 0.370$ closes at 0.997012; the worst sector is now finite charge $s = -1$, not $s \geq 241$.

Control: at $r = 0.371$ the common large sector is 0.971401, while the inherited $s = -1$ column is 1.000856.

Scope: reduced canonical edge generating system; finite breakpoint and column checks validate code, not the theorem.

(d) Complete proof gates at $r = 0.370$
