

The complete first eighth-order heat block is positive, while the dominant degree-eight jet is numerically negative

exact $M = 16$ seven-simplex sum · 35 shuffles · six-variable 1792-state affine lift · final defect bounds still open

(a) Exact suffix-state compression

(b) Exact first-cycle heat enclosure

(c) The complete dominant heat-jet pairing stabilizes by degree eight

Claim boundary: panel (b) is exact; panel (c) is a binary64 convergence pilot. A strict dominant sign still needs defect-resolvent and ninth-derivative bounds.
